We say that code optimization is writing or rewriting code so a program uses the least possible memory or disk space, minimizes its CPU time or network bandwidth, or makes the best use of additional cores. In practice, we sometimes default to another definition: Writing less code.

Your code has no more memory impact by assigning to a stack variable than you would have with fully inlined code. Other optimizations that you might find in C libraries (particularly older ones) where you can have to decide between copying a 2 dimensional array down first or across first is a platform dependent optimization.

## Code Optimization (??)

Machine-dependent optimization is done after the target code has been generated and when the code is transformed according to the target machine architecture. It involves CPU registers and may have absolute memory references rather than relative references. Machine-dependent optimizers put efforts to take maximum advantage of memory hierarchy.
