The `docker run` command first creates a writable container layer over the specified image, and then starts it using the specified command. That is, `docker run` is equivalent to the `API /containers/create then /containers/ (id)/start`. A stopped container can be restarted with all its previous changes intact using `docker start`.

~~Vapor: Deploy - Docker~~

Docker compose, formerly known as Fig, is a tool which can define and run complex applications using Docker. Basically it does the job of creating multiple containers and links between them. Using Docker Compose requires defining the environment required for your app using a Dockerfile and the services required for the app in a '.yaml' file.

~~How to Build and Run your apps using Docker Compose~~

Enter `http://localhost:5000/` in a browser to see the application running. If you're using Docker natively on Linux, Docker Desktop for Mac, or Docker Desktop for Windows, then the web app should now be listening on port 5000 on your Docker daemon host. Point your web browser to `http://localhost:5000` to find the Hello World message. If this doesn't resolve, you can also try `http://127.0.0.1:5000`.

~~Empowering App Development for Developers | Docker~~

Docker Compose has an -f flag where you can pass in the location of the docker-compose.yml file (or a custom file if you happen to name it something different). That means you could run: `docker-compose -f /tmp/myproject/docker-compose.yml up -d` from anywhere on your file system and things will work. I use this a lot in my scripts.
