Finite Difference Method for Solving Differential Equations

The first step is to partition the domain $[0,1]$ into a number of sub-domains or intervals of length h . So, if the number of intervals is equal to n , then $nh = 1$. We denote by x_i the interval end points or nodes, with $x_1 = 0$ and $x_{n+1} = 1$. In general, we have $x_i = (i-1)h$, .

Example 1 - Homogeneous Dirichlet Boundary Conditions We want to use finite differences to approximate the solution of the BVP $u''(x) = -2 \sin(\pi x)$ $0 < x < 1$ $u(0) = 0$; $u(1) = 0$ using $h = 1/4$. Our grid will contain five total grid points $x_0 = 0$; $x_1 = 1/4$; $x_2 = 1/2$; $x_3 = 3/4$; $x_4 = 1$ and three interior points x_1 ; x_2 ; x_3 . Thus we have three unknowns U_1 ; U_2 ; U_3 . We will write the equation at each interior node to

Finite Difference Methods for Boundary Value Problems

A finite difference is a mathematical expression of the form $f(x + b) - f(x + a)$. If a finite difference is divided by $b - a$, one gets a difference quotient. The approximation of derivatives by finite differences plays a central role in finite difference methods for the numerical solution of differential equations, especially boundary value problems.
