Abstract. The advent of nanotechnology, and the need to understand the chemical composition at the nanoscale, has stimulated the convergence of IR and Raman spectroscopy with scanning probe methods, resulting in new nanospectroscopy paradigms. Here we review two such methods, namely photothermal induced resonance (PTIR), also known as AFM-IR and tip-enhanced Raman spectroscopy (TERS).

Raman spectroscopy - Wikipedia

Raman spectroscopy is a complementary technique to infra-red spectroscopy since a lower frequency range of the same radiation as infra-red is selected as the data source during the measurements. Raman spectroscopy is particularly sensitive to the surface complexes forming during the adsorption of organic molecules on metal surfaces [95].

Abstract Established methods for imaging of biological or biomimetic samples, such as fluorescence and optical microscopy, magnetic resonance imaging (MRI), X-ray tomography or positron emission tomography (PET) are currently complemented by infrared (both near-IR and mid-IR) as well as Raman spectroscopic imaging, whether it be on a microscopic or macroscopic scale.
