Since Credit Derivatives are increasingly fundamental, and since in the reduced-form modeling framework much of the technique involved is analogous to interest-rate modeling, Credit Derivatives -- mostly Credit Default Swaps (CDS), CDS Options and Constant Maturity CDS - are discussed, building on the basic short rate-models and market models introduced earlier for the default-free market.

There are a number of theories to explain the nature and determination of the rate of interest. The main theories are: 1. Marginal Productivity Theory: This theory simply states that the marginal productivity of capital determines the rate of interest. Interest is paid because capital is productive and is equal to the marginal product of capital.

Theories for Determining the Rate of Interest

Four main theories of interest rates are: Theory of Austrian School, neoclassical theory, the theory of liquidity and loan theory. The in-depth analysis mainly includes differences of the main theories of interest rate.

INTEREST-RATE MODELS: AN INTRODUCTION

These are the fundamental [assets](#) of interest rate theory, and it is their behaviour we are trying to model. Another very important type of rate frequently quoted in the over-the-counter interest rate markets is the swap rate. There are various types of swap rates, and various conventions dealing with day counts, and so on.

The five theories of interest are as follows: 1. Productivity Theory 2. Abstinence or Waiting Theory 3. Austrian or Agio Theory 4. Classical or Real Theory 5. Loanable Fund Theory. 1. Productivity Theory: According to productivity theory, interest can be defined as a reward for availing the services of capital for the production purpose.

$dr_t = k[\mu - r_t]dt + \sigma p r_t dW(t)$ For the parameters k, μ and σ ranging in a reasonable region, this model implies positive interest rates, but the instantaneous rate is characterized by a noncentral chi-squared distribution. The model is mean reverting as Vasicek's.

Interest Rate Models: Paradigm shifts in recent years

model the prices of the interest rate securities as functions of one or a few state variables, say, spot interest rate, long-term interest rate, spot forward rate, etc. In the so called no arbitrage or term structure interest rate models, the consistencies with the observed initial term structures of interest rates

In financial mathematics, the Black-Karasinski model is a mathematical model of the term structure of interest rates; see short rate model. It is a one-factor model as it describes interest rate movements as driven by a single source of randomness. It belongs to the class of no-arbitrage models, i.e. it can fit today's zero-coupon bond prices, and in its most general form, today's prices for a set of caps, floors or European swaptions. The model was introduced by Fischer Black and Piotr ...
