Module Overview. This next Wireline module begins with an introduction to Wireline logging and what Wireline itself is. Then a history of the wireline is given, showing some of the earliest advances made using this century old technique. And how, thanks to Earle Halliburton, wireline technology pushed forward along with the logging tools.

Wireline logging is performed by lowering a 'logging tool' - or a string of one or more instruments - on the end of a wireline into an oil well (or borehole) and recording petrophysical properties using a variety of sensors. Logging tools developed over the years measure the natural gamma ray, electrical, acoustic, stimulated radioactive responses, electromagnetic, nuclear magnetic resonance, pressure and other properties of the rocks and their contained fluids.

Well logging - Wikipedia

Wireline logging is a conventional form of logging that employs a measurement tool suspended on a cable or wire that suspends the tool and carries the data back to the surface. These logs are taken between drilling episodes and at the end of drilling. Recent developments also allow some measurements to be made during drilling.

Only through openhole logging can a continuous record of such formation properties as porosity, water saturation, and rock type be made, versus depth. In particular, wireline logs can record formation self potential, electrical resistivity, bulk density, natural and induced radioactivity, hydrogen content, and elastic properties.

Soon after each hole was logged, wireline log data were transmitted to LDEO-BRG for processing using a FFASTEST satellite high-speed data link. Data processing at LDEO-BRG includes (1) depth shifting all logs relative to a common datum (i.e., mbsf), (2) corrections specific to individual tools, and (3) quality control and rejection of unrealistic or spurious values.
