Transdermal drug delivery systems are designed to deliver biologically active agents (drugs or cosmeceuticals) through the skin, principally by diffusion, for local internal if not systemic effects. Transdermal API delivery represents an alternative to other forms and routes of drug delivery.

Finally, the use of LFS for transdermal drug delivery has resulted in the ability to increase skin permeability to a greater extent than previously possibly with HFS , making it feasible for pretreatment of the skin to deliver therapeutic levels of drugs, without the need for the additional convection mechanism associated with the simultaneous treatment.

The use of ultrasound for the delivery of drugs to, or through, the skin is commonly known as sonophoresis or phonophoresis. The use of therapeutic and high frequencies of ultrasound (70.7MHz) for sonophoresis (HFS) dates back to as early as the 1950s, while low-frequency sonophoresis (LFS, 20-100kHz) has only been investigated significantly during the past two decades.

A transdermal patch is a medicated adhesive patch that is placed on the skin to deliver a specific dose of medication through the skin and into the bloodstream. Often, this promotes healing to an injured area of the body. An advantage of a transdermal drug delivery route over other types of

Transdermal Drug Delivery System: A Review

First-generation transdermal delivery systems have continued their steady increase in clinical use for delivery of small, lipophilic, low-dose drugs. Second-generation delivery systems using chemical enhancers, noncavitational ultrasound and iontophoresis have also resulted in clinical products; the ability of iontophoresis to control delivery rates in real time provides added functionality.

The main objective of transdermal drug delivery system is to deliver drugs into systemic circulation into the skin through skin at predetermined rate with minimal inter and intra patient variation. 3 Currently transdermal delivery is one of the most promising methods for drug application. 6 It reduces the load that the oral route commonly places on the digestive tract and liver.

A transdermal patch is a medicated adhesive patch that is placed on the skin to deliver a specific dose of medication through the skin and into the bloodstream. Often, this promotes healing to an injured area of the body. An advantage of a transdermal drug delivery route over other types of medication delivery such as oral, topical, intravenous, intramuscular, etc. is that the patch provides a controlled release of the medication into the patient, usually through either a porous membrane coverin

Abstract Electroporation is an important physical technique to improve drug transdermal delivery, although its mechanism remains unclear. Here, some types of polar drugs, including aspirin, diclofenac sodium, metformin hydrochloride, ibuprofen and zidovudine, were used as the model drugs for the exploration of electroporation mechanisms.

Many formulators have investigated the skin permeation mechanism of many drugs using NEs and microemulsions (MEs) as delivery systems [20, 28, 29]. NEs and MEs share similar components in different ratios and the same penetration mechanisms. Their main difference lies in their droplet shape, size distribution, and kinetic stability [30].
