The development of memory is a lifelong process that continues through adulthood. Development etymologically refers to a progressive unfolding. Memory development tends to focus on periods of infancy, toddlers, children, and adolescents, yet the developmental progression of memory in adults and older adults is also circumscribed under the umbrella of memory development. The development of memory in children becomes evident within the first 3 years of a child's life as they show considerable adva

Because most memories in babies are only stored as short-term memories, the development of a child's "first memory" doesn't generally occur until about age 3. The memories of a baby are left inaccessible, since the brain structures that hold them permanently in the mind are not formed until later.

Memory Development in Babies | Healthfully

In general, we have discovered that although short-term memory emerges early in life, it rapidly develops between 4 and 10 months of age. These early limits on short-term memory might be especially important for helping young babies deal with the overwhelming amount of new information they encounter each day.

Infant Memory Development - Infant Cognition Lab

There are two basic types of explicit, or declarative, memory. First, short term or working memory. Think of this as the focus of current attention, or what you are actively thinking about right now. Second, long term memory which is broken down further into semantic memory (facts) and episodic memory (specific events).
