Behavioural biologists face an important choice at the onset of any research project: what sample size should be used to address the questions being posed. The sample size selected – regardless of the research question being asked or the statistical approach used – necessarily impacts the precision of parameter estimates (e.g. means or effect sizes).

In statistics, the Kolmogorov–Smirnov test (K–S test or KS test) is a nonparametric test of the equality of continuous (or discontinuous, see Section 2.2), one-dimensional probability distributions that can be used to compare a sample with a reference probability distribution (one-sample K–S test), or to compare two samples (two-sample K–S test).

Kolmogorov–Smirnov test - Wikipedia

In statistics, sometimes the covariance matrix of a multivariate random variable is not known but has to be estimated. Estimation of covariance matrices then deals with the question of how to approximate the actual covariance matrix on the basis of a sample from the multivariate distribution. Simple cases, where observations are complete, can be dealt with by using the sample covariance matrix.
