Ohm's Law would suggest an infinite current (current = voltage divided by zero resistance). Yet, the experiment described yields only a modest amount of current. If you think that the wire used in the experiment is not resistance-less (i.e. it does have resistance), and that this accounts for the disparity between the predicted and measured amounts of current, you are partially correct.

Ohm's law states a correlation between voltage, V (volts), and current, i (amps) if a resistor rests within a current range and does not heat up. This can be expressed by: $V = iR$ [1] Where R is the resistance in ohms. Unmeasured variables, such as temperature, are critical, as they could alter the linearity of the relationship.

Ohms law can be used to identify the relationship between voltage, current, and resistance in any DC electrical circuit discovered by a German physicist named, Georg Ohm. This law states that voltage is equal to the product of the total current and the total resistance. The equation for this law is often presented in a triangle where the voltage is on the top, current and resistance are on the bottom with
