Seed Germination Plant

Phytochrome control of cucumber seed germination is temperature-dependent. A prolonged exposure to radiation from broad spectrum far red sources ($P_{fr}/P = 0.05$ to 0.07) prevents germination at temperatures below 20 C. Above 20 C there is no inhibition and it appears as if there is an escape from phytochrome control.

Phytochrome And Seed

Seed germination of many plant species is influenced by light. Of the various photoreceptor systems, phytochrome plays an especially important role in seed germination. The existence of at least five phytochrome genes has led to the proposal that different members of the family have different roles in the photoregulation of seed germination.

Phytochrome and Seed Germination: VI. Phytochrome and ...

The control of seed germination by red and far-red light is one of the earliest documented phytochrome-mediated processes. Phytochrome is now known to be a small family of photoreceptors whose apoproteins are encoded by different genes. Phytochrome B (phyB) is present in dry seeds and affects germination of dark imbibed seeds but other phytochromes could also be involved. Phytochrome A (phyA) appears after several hours of

some species (epigeous). This growth is rapid until the plant penetrates the soil and is exposed to light.

Phytochrome - plant phys

Phytochrome is a regulatory pigment which controls many light-dependent development processes in plants besides germination in light-sensitive seeds. These include photomorphogenesis (light-regulated developmental process) and flowering in a variety of plants. Phytochrome and Reversible Red-Far-red Control of Germination:

Phytochromes control many aspects of plant development. They regulate the germination of seeds (photoblasty), the synthesis of chlorophyll, the elongation of seedlings, the size, shape and number and movement of leaves and the timing of flowering in adult plants. Phytochromes are widely expressed across many tissues and developmental stages.

Phytochrome is now known to be a small family of photoreceptors whose apoproteins are encoded by different genes. Phytochrome B (phyB) is present in dry seeds and affects germination of dark imbibed seeds.

Phytochromes and seed germination

Phytochrome is a pigment found in plants that allows the plants to detect light. It is a crucial element to plant survival and is used to regulate flowering and to set the plant's circadian rhythm, among other things.

Phytochrome (Pr) Plants rely on light for their food and to ensure growth.

What is Phytochrome (Pr)? - Definition from MaximumYield

The cryptogamic phytochromes identified to date typically show the structure common to seed plant phytochromes with a chromophore-bearing region, a hinge-like region, a PAS domain, and a histidine kinase-like domain at the C terminus.
