In ray tracing, this is usually done with an `_instance_`. An instance is a geometric primitive that has been moved or rotated somehow. This is especially easy in ray tracing because we don't move anything; instead we move the rays in the opposite direction. For example, consider a `_translation_` (often called a `_move_`).

Ray Tracing: the Next Week in Futhark. This is a port of Ray Tracing: the Next Week to the purely functional data-parallel language Futhark, which can generate efficient GPU code. See also the Futhark implementation of Ray Tracing in One Weekend. The scene below took about 7 minutes to render on an AMD Vega 64 GPU, and is 1000x1000 pixels, with 5000 samples per pixel, and a maximum of 50 reflections per ray.

a full-featured ray tracer, but it does have the indirect lighting which has made ray tracing a staple in movies. Follow these steps, and the architecture of the ray tracer you produce will be good for extending to a more extensive ray tracer if you get excited and want to pursue that. When somebody says "ray tracing" it could mean many things.

Ray Tracing: The Next Week BVH question. I am stepping through Peter Shirley's Ray Tracing: The Next Week, specifically the `random_scene ()` where several stationary and moving spheres are created. It is using BVH to check if a ray hits any object. The problem I am having is, the code traverses down the BVH tree, finds a leaf and checks the `aabb` of the object (not the `hit ()` function of the sphere but its `bounding_box`).
