Signal denoising based on empirical mode decomposition ...

The empirical mode decomposition (EMD) algorithm is a technique designed by Wu and Huang primarily for decomposing the nonlinear and non-stationary signals into a series of intrinsic mode functions (IMFs). It has been used to address several problems in the field of science and engineering.

for stress wave denoising. The empirical mode decomposition (EMD) algorithm is a technique designed by Wu and Huang primarily for decomposing the nonlinear and non-stationary signals into a series of intrinsic mode functions (IMFs) [10]. It has been used to address several problems in the field of science and engineering [11].

Stress Wave Signal Denoising Using Ensemble Empirical Mode ...

Traditional denoising methods based on empirical mode decomposition (EMD) are mainly classified into two categories: the partial reconstruction of relevant modes and the whole reconstruction of all filtered modes [26,27]. However, when the signal-to-noise ratio (SNR) of the signal is high, the useful signal is also decomposed into lower-order intrinsic mode functions (IMFs), in which case the useful information may be mistaken for the discarded irrelevant information.

In this paper, an ensemble empirical mode decomposition (EEMD) based approach with the aim of signal denoising was proposed and applied to stress wave signals. The method defined the time interval between two adjacent zero-crossings within the intrinsic mode function (IMF) as the instantaneous half period (IHP) and used it as a criterion to detect and classify the noise oscillations.

Stress Wave Signal Denoising Using Ensemble Empirical Mode ...

Empirical Mode Decomposition (EMD) is an adaptive and fully data driven method, which is developed to analyze non-linear and non-stationary signals. It decomposes the signal in fast and slow oscillations called Intrinsic Mode functions (IMFs). However, EMD suffers from a problem known as "mode mixing".

In this paper, we propose a new ECG enhancement method based on the recently developed empirical mode decomposition (EMD). The proposed EMD-based method is able to remove both high-frequency noise and BW with minimum signal distortion. The method is validated through experiments on the MIT-BIH databases.

The technique utilized is the empirical wavelet transform, which is a new method used to compute the building modes of a given signal. Its performance as a filter is compared to the standard linear filters and empirical mode decomposition. The results show that EWT delivers a better performance.

This study explores the data-driven properties of the empirical mode decomposition (EMD) for signal denoising. EMD is an acknowledged procedure which has been widely used for non-stationary and nonlinear signal processing. The main idea of the EMD method is to decompose the analyzed signal into components without using expansion functions.

Empirical Mode Decomposition in Discrete Time Signals ...

Recently, a new signal analysis method called Empirical mode decomposition (EMD) has been introduced by Huang et al. for analyzing data from nonstationary and nonlinear processes. The major advantage of EMD is that the basis functions used to decompose a signal are not predefined but adaptively derived from the signal itself.
