~~In time series forecasting, data smoothing is a statistical technique that involves removing outliers from a time series data set to make a pattern more visible. Inherent in the collection of data taken over time is some form of random variation. Smoothing data removes or reduces random variation and shows underlying trends and cyclic components.~~

~~Exponential smoothing is useful method for forecasting time series. The basic idea is to predict future values of time series as weighted average of past observations, where weights decrease exponentially with time: $y_t = a y_{t-1} + (1-a) y_{t-2} + a (1-a)^2 y_{t-3} + \dots$, where $a (0,1)$ is smoothing parameter which should be estimated.~~

The time series type of forecasting methods, such as exponential smoothing, moving average and trend analysis, employ historical data to estimate future outcomes. A time series is a group of data that's recorded over a specified period, such as a company's sales by quarter since the year 2000 or the annual production of Coca Cola since 1975.

Time series forecasting is a technique for the prediction of events through a sequence of time. The technique is used across many fields of study, from geology to economics. The techniques predict future events by analyzing the trends of the past, on the assumption that the future trends will hold similar to historical trends.

Time series forecasting is an important area of machine learning that is often neglected. It is important because there are so many prediction problems that involve a time component. These problems are neglected because it is this time component that makes time series problems more difficult to handle.

In cases where the time series lacks significant trends, smoothing techniques can be used for demand forecasting. Smoothing techniques are used to eliminate a random variation from the historical demand. This helps in identifying demand patterns and demand levels that can be used to estimate future demand.

If a forecasting method is used to predict the value of the time series at some time t , then we will denote the predicted value by $X^*(t)$. Hence, the error in our prediction would be $X(t) - X^*(t)$, the difference between the actual value and the predicted value. The ultimate test of any forecasting method is the size of these errors.
